#### Abstract

The notion of Intuitionistic Fuzzy Set (IFS for short) theory by Krassimir Atanassov strikes a paradigm shift in solving decision making problems, which is one of the crucial problems in our real life. Ranking of IFS and Interval Valued Intuitionistic Fuzzy Sets (IVIFS for short) is very often required in decision making. In this paper, we develop an aggregation operator for aggregating Intuitionistic fuzzy sets as well as interval valued intuitionistic fuzzy sets. It appears to be more elegant and simple than the existing aggregation operators. We also propose a score function and an accuracy function to rank the aggregated alternatives. It is illustrated with an examples.

Keywords: Intuitionistic fuzzy sets, Interval-valued intuitionistic fuzzy sets, Aggregation operator.
AMS Classification: 03E72.

## 1 Introduction

Following the introduction of Fuzzy set by Zadeh in 1965, K. Atanassov introduced the notion of IFS (see [1, 2]) which has been found a better tool to model decision problems. Multicriteria decision making methods based on IFS theoretical tools were introduced in the decision theory in 2007 by Z. S. Xu, [5]. Xu introduced different types of aggregation operators. This was extended to IVIFS, [7].

In this paper, we propose an aggregation operator, score function and an accuracy function for an intuitionistic fuzzy set.

## 2 Preliminaries

Definition 2.1, [2]. Let $X$ be a given set. An Intuitionistic fuzzy set $A$ in $X$ is given by $A=\left\{\left(x, \mu_{A}(x), \nu_{A}(x)\right) \mid x \in X\right\}$ where $\mu_{A}, \nu_{A}: X \rightarrow[0,1], \mu_{A}(x)$ is the degree of membership of the element $x$ in $A$ and $\nu_{A}(x)$ is the degree of non-membership of $x$ in $A$, and 0 $\leq \mu_{A}(x)+\nu_{A}(x) \leq 1$. For each $x \in X, \pi_{A}(x)=1-\mu_{A}(x)-\nu_{A}(x)$ is the degree of hesitation.
Definition 2.2, [2]. Let $D[0,1]$ be the set of all closed subintervals of the interval $[0,1]$. Let $X \neq \phi$ be a given set. An interval valued intuitionistic fuzzy set $A$ in $X$ is given by $A=$ $\left\{\left(x, \mu_{A}(x), \nu_{A}(x)\right): x \in X\right\}$, where $\mu_{A}: X \rightarrow D[0,1], \nu_{A}: X \rightarrow D[0,1]$ with the condition $0 \leq \sup _{x} \mu_{A}(x)+\sup _{x} \nu_{A}(x) \leq 1$. The intervals $\mu_{A}(x)$ and $\nu_{A}(x)$ denote, respectively, the degree of belongingness and the degree of non-belongingness of the element $x$ to the set $A$. Thus, for each $x \in X, \mu_{A}(x)$ and $\nu_{A}(x)$ are closed intervals whose lower and upper end points are respectively, denoted by $\mu_{A L}(x), \mu_{A U}(x)$ and $\nu_{A L}(x), \nu_{A U}(x)$.
$A$ can also be denoted by $A=\left\{\left(x,\left[\mu_{A L}(x), \mu_{A U}(x)\right],\left[\nu_{A L}(x), \nu_{A U}(x)\right]\right): x \in X\right\}$, where $0 \leq \mu_{A U}(x)+\nu_{A U}(x) \leq 1, \mu_{A L}(x) \geq 0$ and $\nu_{A L}(x) \geq 0$.

We will denote the set of all the IVIFS in $X$ by $\operatorname{IVIFS}(X)$.
Now we define some aggregation operators which are already in literature.
Definition 2.3, [7]. The arithmetic average operator for alternatives $A_{j}(j=1,2, \ldots, n)$ is defined by $F\left(A_{1}, A_{2}, \ldots, A_{n}\right)=\left(1-\Pi\left(1-\mu_{A j}(x)\right), \Pi\left(\nu_{A j}(x)\right)\right)$. And the geometric average operator is defined by $G\left(A_{1}, A_{2}, \ldots, A_{n}\right)=\left(\prod \mu_{A j}(x), 1-\Pi\left(1-\nu_{A j}(x)\right)\right)$.
Definition 2.4, [7]. The weighted arithmetic average operator for alternatives $A_{j}$ $(j=1,2, \ldots, n)$ is defined by $F_{w}\left(A_{1}, A_{2}, \ldots, A_{n}\right)=\left(1-\prod\left(1-\mu_{A j}(x)\right)^{w_{j}}, \prod\left(\nu_{A j}(x)\right)^{w_{j}}\right)$, where $w_{j}$ is the weight of $A_{j}(j=1,2, \ldots, n), w_{j} \in[0,1]$ and $\sum_{j=1}^{n} w_{j}=1$. Also the weighted geometric average operator is defined by

$$
G_{w}\left(A_{1}, A_{2}, \ldots, A_{n}\right)=\left(\prod\left(\mu_{A j}(x)\right)^{w_{j}}, 1-\prod\left(1-\nu_{A j}(x)\right)^{w_{j}}\right)
$$

where $w_{j}$ is the weight of $A_{j}(j=1,2, \ldots, n), w_{j} \in[0,1]$ and $\sum_{j=1}^{n} w_{j}=1$.
Definition 2.5, [7]. Let $A_{j}(j=1,2, \ldots, n) \in \operatorname{IVIFS}(X)$. The weighted geometric average operator for IVIFSs is defined by

$$
\begin{gathered}
G_{w}\left(A_{1}, A_{2}, A_{3}, \ldots, A_{n}\right)=\Pi A_{j}{ }^{w_{j}}= \\
=\left(\left[\Pi \mu_{A_{j} L} L^{w_{j}}(x), \Pi \mu_{A_{j} U^{w_{j}}}(x)\right],\left[1-\Pi\left(1-\nu_{A_{j} L}(x)\right)^{w_{j}}, 1-\Pi\left(1-\nu_{A_{j} U}(x)\right)^{w_{j}}\right]\right)
\end{gathered}
$$

where $w_{j}$ is the weight of $A_{j}(j=1,2, \ldots, n), w_{j} \in[0,1]$ and $\sum_{i=1}^{n} w_{j}=1$.

By assuming $w_{j}=1 / n(j=1,2, \ldots, n)$ then $G_{w}$ is called an geometric average operator for $A_{1}, A_{2}, \ldots, A_{n}$. Clearly $G_{w}$ is an IVIFS.

Also, for $A_{j}(j=1,2, \ldots, n) \in \operatorname{IVIFS}(X)$.The weighted arithmetic average operator is defined by

$$
\begin{gathered}
F_{w}\left(A_{1}, A_{2}, A_{3}, \ldots, A_{n}\right)=\sum_{j} w_{j} A_{j} \\
\left(\left[1-\Pi\left(1-\mu_{A_{j} L}(x)\right)^{w_{j}}, 1-\Pi\left(1-\mu_{A_{j} U}(x)\right)^{w_{j}}\right],\left[\Pi \nu_{A_{j} L}{ }^{w_{j}}(x), \Pi \nu_{A_{j} U}{ }^{w_{j}}(x)\right]\right),
\end{gathered}
$$

where $w_{j}$ is the weight of $A_{j}(j=1,2, \ldots, n), w_{j} \in[0,1]$ and $\sum_{i=1}^{n} w_{j}=1$.
By assuming $w_{j}=1 / n(j=1,2, . . n)$ then $F_{w}$ is called an arithmetic average operator for $A_{1}, A_{2}, . . A_{n}$.

## 3 New aggregation operators, score function and accuracy function

Definition 3.1. For IF alternatives $A_{i}, i=1,2, \ldots, n$ based on criteria $C_{j}, j=1,2, \ldots, m$ if $a_{i j}$ indicates the degree that the alternative $A_{i}$ satisfies the criterion $C_{j}$ and $b_{i j}$ indicates the degree that the alternative $A_{i}$ does not satisfies the criterion $C_{j}$. Then the mean based aggregation operator denoted by $A_{i m}=\left[A_{i l}, A_{i u}\right]$ where, $A_{i l}=\sum w_{j} a_{i j}$ and $A_{i u}=\sum w_{j}\left(1-b_{i j}\right) . w_{j}$ are the weights for the criteria $C_{j}$, with $\sum_{j=1}^{m} w_{j}=1$.
Definition 3.2. For IVIF alternatives $A_{i}, i=1,2, \ldots, n$ based on criteria $C_{j}$, $j=1,2, \ldots, m$, if $\left[a_{i j}, b_{i j}\right]$ indicates the degree that the alternative $A_{i}$ satisfies the criterion $C_{j}$ and $\left[c_{i j}, d_{i j}\right]$ indicates the degree that the alternative $A_{i}$ does not satisfies the criterion $C_{j}$. Then, the mean based aggregation operator denoted by $A_{i m}=\left[A_{i l}, A_{i u}\right]$, where,

$$
A_{i l}=\frac{\sum w_{j}\left(a_{i j}+b_{i j}\right)}{2}
$$

and

$$
A_{i u}=\sum w_{j}\left(1-\frac{c_{i j}+d_{i j}}{2}\right),
$$

where $w_{j}$ are the weights for the criteria $C_{j}$, with $\sum w_{j}=1$.
Note 3.3. $A_{\text {im }}=\left[A_{i l}, A_{i u}\right] \subseteq[0,1]$.
Definition 3.4. For an alternative $A_{i}$, whose mean based aggregated value given by $A_{i m}=\left[A_{i l}, A_{i u}\right]$, score for $A_{i}$ is $S\left(A_{i}\right)=\frac{A_{i l}+A_{i u}}{2}$.
Definition 3.5. For alternatives $A_{i}, A_{j}$, with score given by $S\left(A_{i}\right)=\frac{A_{i l}+A_{i u}}{2}$, if score of $A_{i}=$ Score of $A_{j}$, then we can compare them by comparing their $A_{i l}$. In other words, if score function of two alternatives are equal, then their accuracy function can be given by $A_{c}\left(A_{i}\right)=A_{i l}$ the lower limit of the aggregated value.

Theorem 3.6. For two comparable alternatives $A_{1}$ and $A_{2}$ based on criteria $C_{1}$ and $C_{2}$ such that $A_{1} \supset A_{2}$, then their scores $S\left(A_{1}\right)>S\left(A_{2}\right)$.

Proof: Let the IVIF alternatives $A_{1}$ and $A_{2}$ be such that $a_{11}>a_{21}, a_{12}>a_{22}, b_{11}>b_{21}, b_{12}>$ $b_{22}, c_{11}<c_{21}, c_{12}<c_{22}$, and $d_{11}<d_{21}, d_{12}<d_{22}$. Then the score of $A_{1}$ is

$$
\begin{align*}
S\left(A_{1}\right) & =\frac{A_{1 l}+A_{1 u}}{2}=\frac{\sum w_{j}\left(a_{1 j}+b_{1 j}\right)}{2}+\sum w_{j}\left(1-\left(\frac{c_{1 j}+d_{1 j}}{2}\right)\right) \\
& =\frac{w_{1}\left(a_{11}+b_{11}\right)}{2}+\frac{w_{2}\left(a_{12}+b_{12}\right)}{2}+w_{1}\left(1-\left(\frac{c_{11}+d_{11}}{2}\right)\right)+w_{2}\left(1-\left(\frac{c_{12}+d_{12}}{2}\right)\right) \tag{1}
\end{align*}
$$

And the score of $A_{2}$ is

$$
\begin{align*}
S\left(A_{2}\right) & =\frac{A_{2 l}+A_{2 u}}{2}=\frac{\sum w_{j}\left(a_{2 j}+b_{2 j}\right)}{2}+\sum w_{j}\left(1-\left(\frac{c_{2 j}+d_{2 j}}{2}\right)\right)  \tag{2}\\
& =\frac{w_{1}\left(a_{21}+b_{21}\right)}{2}+\frac{w_{2}\left(a_{22}+b_{22}\right)}{2}+w_{1}\left(1-\left(\frac{c_{21}+d_{21}}{2}\right)\right)+w_{2}\left(1-\left(\frac{c_{22}+d_{22}}{2}\right)\right)
\end{align*}
$$

From (1) and (2), $S\left(A_{1}\right)-S\left(A_{2}\right)$ is positive.
Theorem 3.7 For two comparable alternatives $A_{1}$ and $A_{2}$ based on criteria $C_{1}$ and $C_{2}$ such that $A_{1} \supset A_{2}$, then accuracy value of $A_{1}$ is greater than that of $A_{2}$.

Proof: Let the alternatives $A_{1}$ and $A_{2}$ be such that $a_{11}>a_{21}, a_{12}>a_{22}, b_{11}>b_{21}$, $b_{12}>b_{22}, c_{11}<c_{21}, c_{12}<c_{22}$, and $d_{11}<d_{21}, d_{12}<d_{22}$.

We denote the accuracy of $A_{1}$ by $A_{c}\left(A_{1}\right)$ and that of $A_{2}$ by $A_{c}\left(A_{2}\right)$.
Then

$$
\begin{gathered}
A_{c}\left(A_{1}\right)-A_{c}\left(A_{2}\right)= \\
=\left(\frac{w_{1}\left(a_{11}+b_{11}\right)}{2}+\frac{w_{2}\left(a_{12}+b_{12}\right)}{2}\right)-\left(\frac{w_{1}\left(a_{21}+b_{21}\right)}{2}+\frac{w_{2}\left(a_{22}+b_{22}\right)}{2}\right)
\end{gathered}
$$

is a positive number. Which shows $A_{1}$ is better than $A_{2}$.

### 3.1 Illustration 1

For two IF alternatives $A_{1}$ and $A_{2}$ based on two weighted criteria $C_{1}$ (weight $w_{1}=0.4$ ) and $C_{2}$ (weight $w_{2}=0.6$ ) as follows

$$
\begin{array}{ccc} 
& C_{1} & C_{2} \\
A_{1} & (0.4,0.5) & (0.55,0.25) \\
A_{2} & (0.3,0.6) & (0.5,0.4)
\end{array}
$$

Based on our aggregation operator we can find the lower limit for the aggregated interval for $A_{1}$ as $A_{1 l}=0.4 \times 0.4+0.6 \times 0.55=0.49$. The upper limit for the aggregated interval for $A_{1}$, i.e., $A_{1 u}=0.4 \times 0.5+0.6 \times 0.75=0.65$. Therefore, aggregated interval corresponding to $A_{1}$ is $[0.49,0.65]$. Similarly for $A_{2}, A_{2 l}=0.42$ and $A_{2 u}=0.52$. Therefore, aggregated interval corresponding to $A_{2}$ is $[0.42,0.52]$. The score for $A_{1}$ is $\frac{0.49+0.65}{2}=0.57$ and score for $A_{2}$ is 0.47 . In this method, the alternative $A_{1}$ is better than $A_{2}$.

### 3.2 Illustration 2

For two IVIF alternatives $A_{1}$ and $A_{2}$ based on two weighted criteria $C_{1}$ (weight $w_{1}=0.4$ ) and $C_{2}$ (weight $w_{2}=0.6$ ) as follows

|  | $C_{1}$ | $C_{2}$ |
| :---: | :---: | :---: |
| $A_{1}$ | $[0.4,0.5],[0.2,0.3]$ | $[0.6,0.7],[0.1,0.2]$ |
| $A_{2}$ | $[0.3,0.4],[0.5,0.55]$ | $[0.4,0.5],[0.3,0.5]$ |

The lower limit for the aggregated interval for $A_{1}$ as $A_{1 l}=0.4 \times 0.45+0.6 \times 0.65=0.57$. The upper limit for the aggregated interval for $A_{1}$ as $A_{1 u}=0.4 \times 0.75+0.6 \times 0.85=0.81$. Therefore, aggregated interval corresponding to $A_{1}$ is $[0.57,0.81]$. Similarly for $A_{2}$, the aggregated interval is $[0.41,0.55]$. The score for $A_{1}$ is $\frac{0.57+0.81}{2}=0.69$ and score for $A_{2}$ is 0.48 . In this method, the alternative $A_{1}$ is better than $A_{2}$. In both the above cases, no need to find the accuracy values of the alternatives. If necessary, use Definition 3.5.

## 4 Conclusion

Decision making is one of the crucial problems in real life. Usually we have to deal with multicriteria decision making problems. In this paper, we propose an aggregation operator to aggregate the criteria for intuitionistic fuzzy alternatives as well as for interval valued intuitionistic fuzzy alternatives. We also propose score function and accuracy function to rank the alternatives.
